

QUEUES & BREADTH-FIRST TRAVERSAL COMPLETE BINARY TREES

Problem Solving with Computers-II

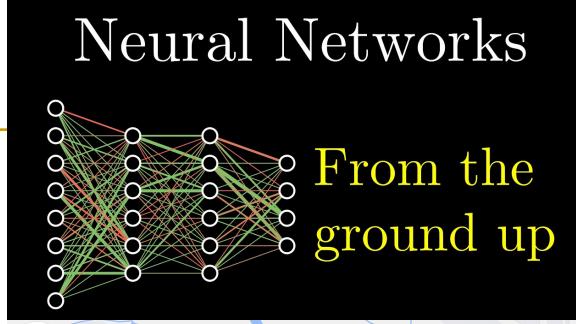

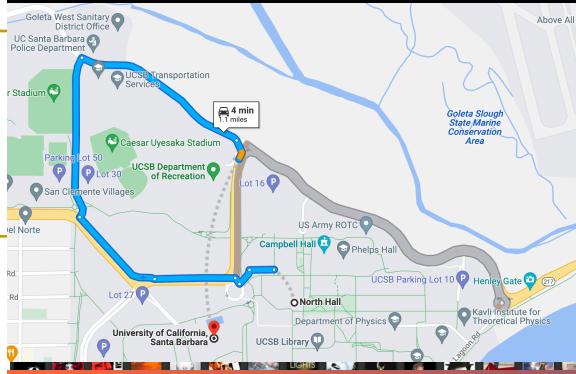

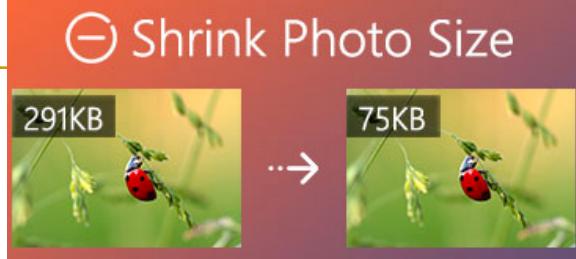

```
#include <iostream>
using namespace std;

int main(){
    cout<<"Hola Facebook\n";
    return 0;
}
```

From Data Structures to Real-World Applications

Data Structure	Algorithm	Real-World Application	
Queue	Breadth-First Search (BFS)	 Machine Learning (PA03: Prediction in NNs)	 Neural Networks From the ground up
Queue	Round-Robin Scheduling	 Operating Systems (Task scheduling)	 Above All Aviat
Priority Queue	Dijkstra's Algorithm	 GPS Navigation (Shortest path)	
Priority Queue	Huffman Coding	 Data Compression (ZIP, JPEG, MP3)	
Your choice!	You design!	Querying a movie dataset (PA02)	

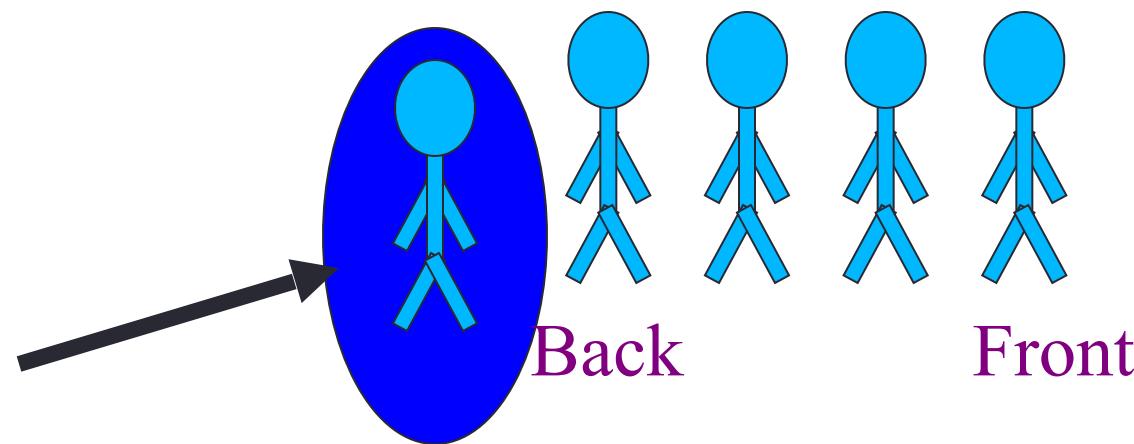

Queue: First come First Serve

- A queue is like a queue of people waiting to be serviced
- The queue has a **front** and a **back**.

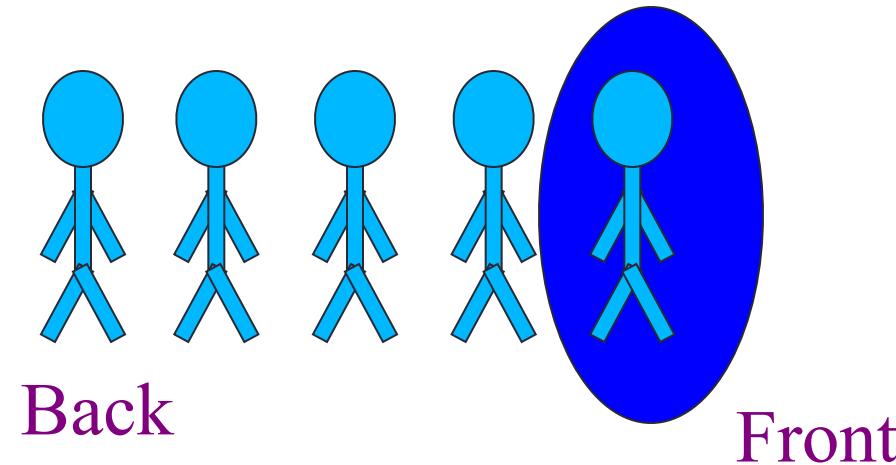

Queue Operations: push, pop, front, back

New people must enter the queue at the back. The C++ queue class calls this a push operation.

Queue Operations: push, pop, front, back

- To check the item in the front of the queue, use **front()**
- To check the item at the back of the queue, use **back()**
- When an item is taken from the queue, it always comes from the front.
- To delete an element from the front of the queue, use **pop()**

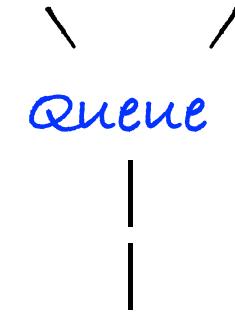

Queue Operations: empty(), push, pop, front, back: O(1)

```
std::queue<int> q;
q.empty(); //true
q.push(1);
// push 2, 3, 4, 5
q.front();
q.back();
q.pop();
```

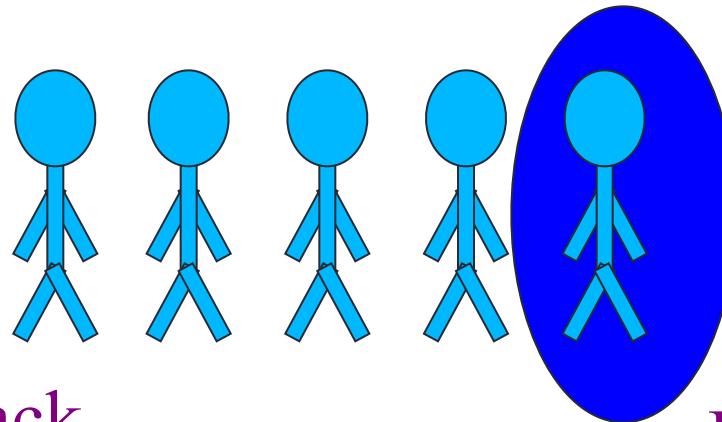

Algorithms: Breadth First Search Task Scheduling

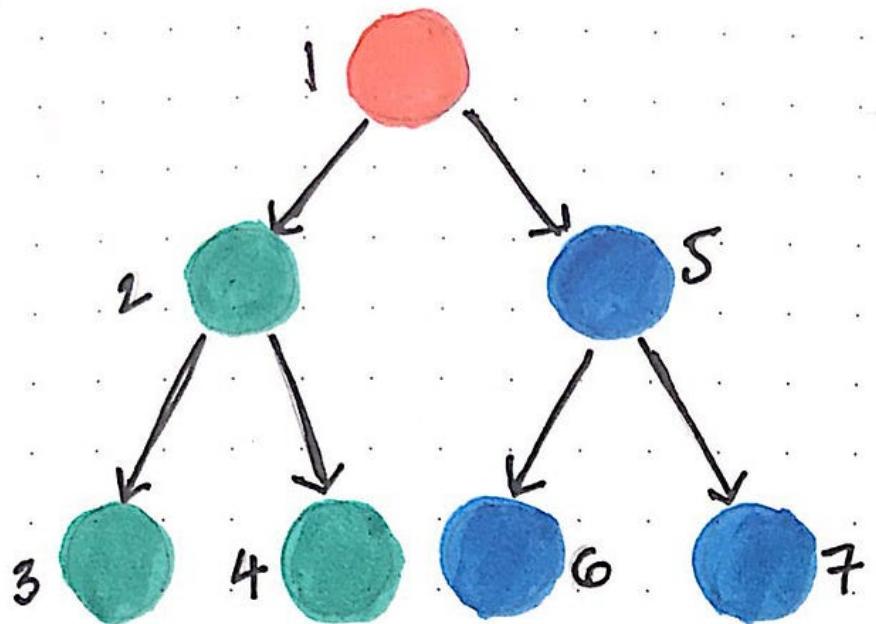

ADT:

Data structure:

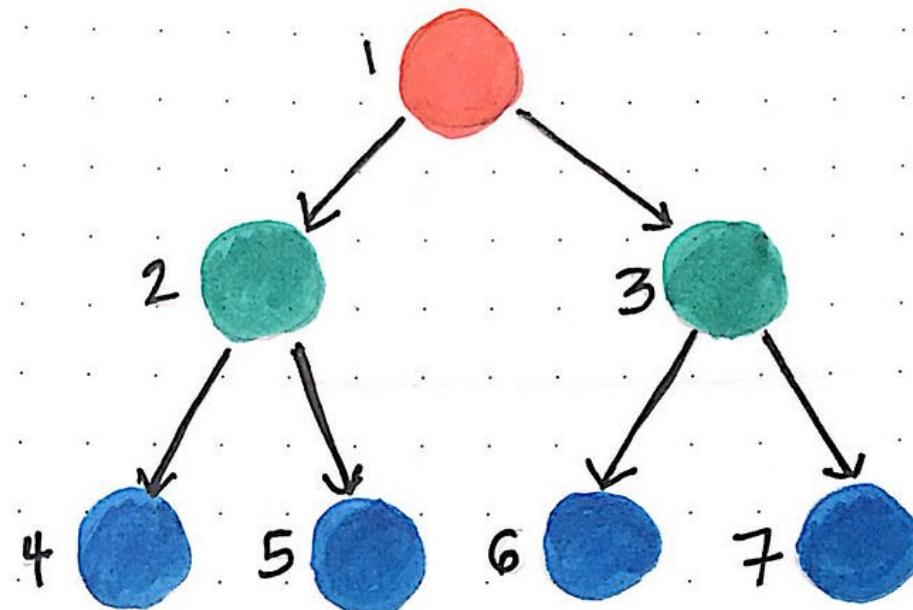

Linked list or vector

Depth-first search

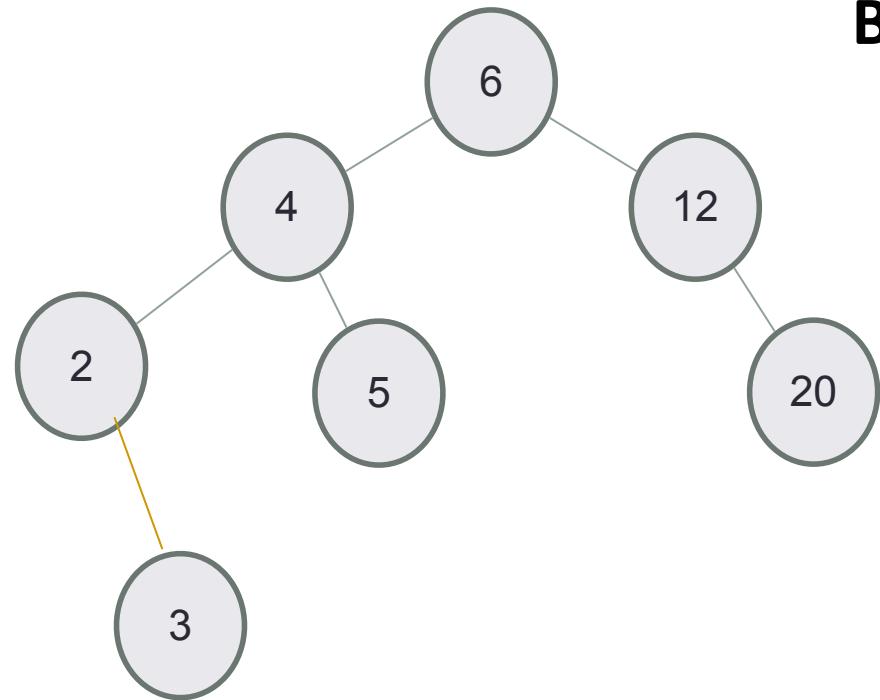

- Traverse through left subtree(s) first, then traverse through the right subtree(s).

Breadth-first search

- Traverse through one level of children nodes, then traverse through the level of grandchildren nodes (and so on...).

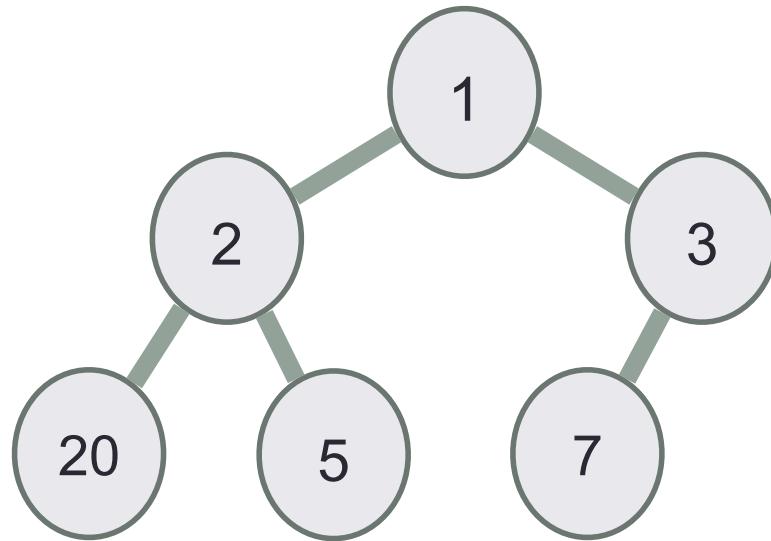

Breadth-first traversal/search

BFS Algo:

- Create an empty **queue**.
- Insert the **root** into the **queue**.
- While queue is not empty,
 - Print the key in the front of the queue
 - Insert all the children of the node into the queue.
 - Pop the front node from the queue

Breadth-first traversal

BFS Algo (store output in a vector: result):

- Create an empty **queue**.
- Create an empty **vector called result**.
- Insert the **root** into the **queue**.
- While queue is not empty,
 - **Append the key in the front of the queue to result**
 - Insert all the children of the node into the queue.
 - Pop the front node from the queue

Activity 1:

1. Trace BFS for the given tree, show how the queue evolves
2. What is the resulting vector?

Connecting: vector and Google maps!

Applications: Machine Learning, Operating Systems, Image compression, Google maps

Algorithms: BFS Task Scheduling

Huffman Coding Dijkstra's Shortest Path

ADT: Queue

Datastructure: Linked list or vector

Priority Queue

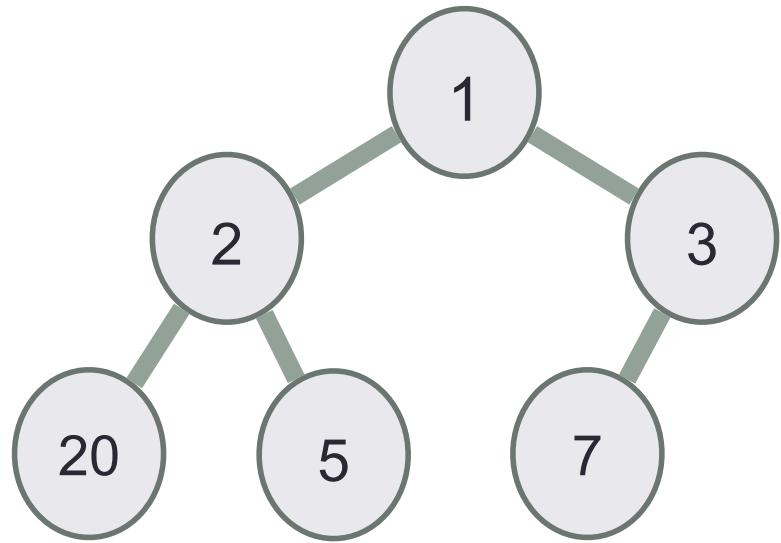

Binary Heap

Complete Binary Tree

vector

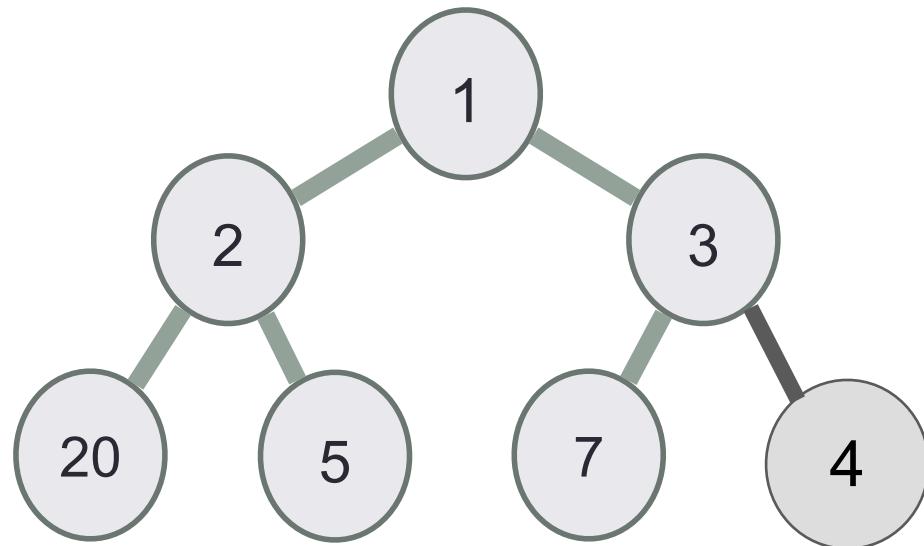

The priority_queue abstract data type (ADT) is implemented as a complete binary tree. Complete binary tree is efficiently represented as a vector, by indexing keys in BFS order.

Structure behind a priority queue

Complete Binary Tree:

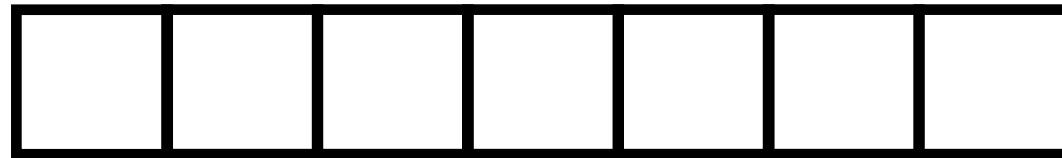

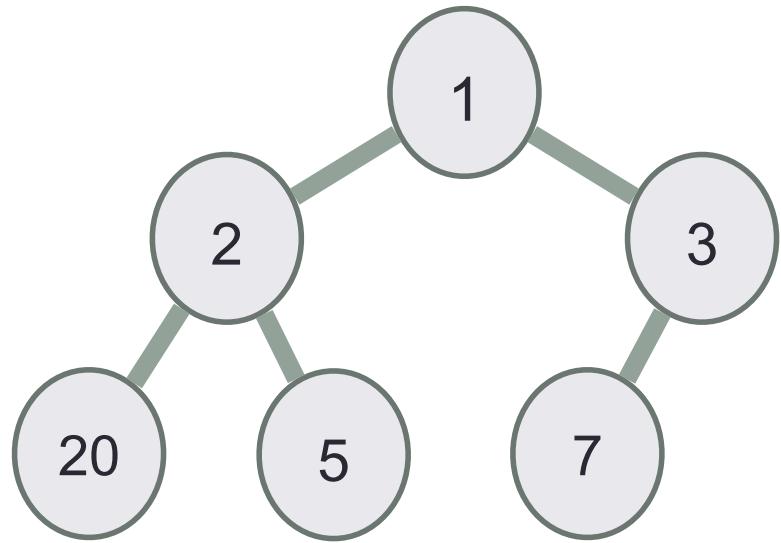

Every level is completely filled (except possibly the last level), and all nodes on the last level are as far left as possible

Full Binary Tree: A complete binary tree whose last level is completely filled

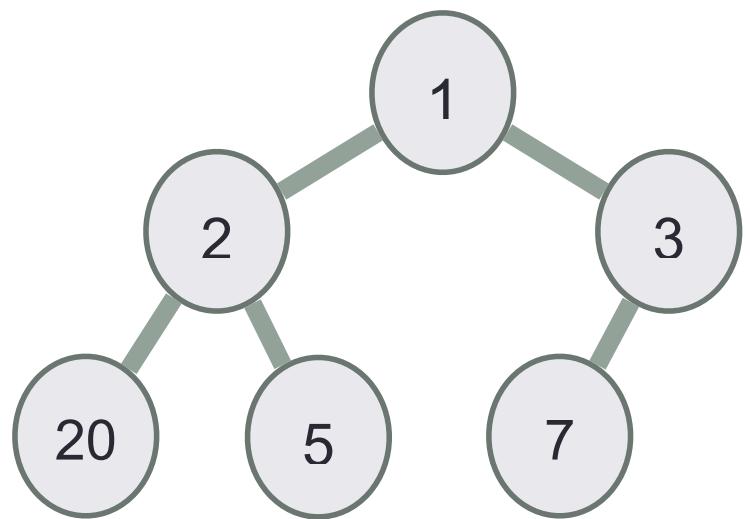

Complete/full binary trees are **balanced trees!**

Representing a complete binary tree as a vector!

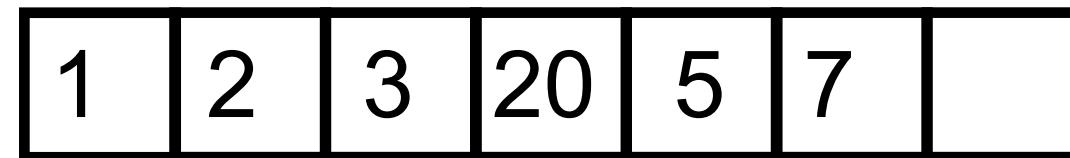

- How is the index of each key related to the index of its parent?
- How is the index of each key related to the indices of its left and right child?

Representing a complete binary tree as a vector!

index
key
parent
left child
right child

Root is at index 0

For a key at index i , index of its

- **parent is $\lfloor (i - 1)/2 \rfloor$**
- **left child is $2i + 1$**
- **right child is $2i + 2$**

Activity 2: For a key at index i , determine the indices of its parent and children.

Traverse up the tree using the vector (only)!

Root is at index 0

For a key at index i , index of its

- **parent is** $\lfloor (i - 1)/2 \rfloor$
- **left child is** $2i + 1$
- **right child is** $2i + 2$

1	2	3	20	5	7	
---	---	---	----	---	---	--

Activity 3: Starting at the last node in the last level (7), write the indices of the keys visited on the path to the root node with key (1):

- A. 5, 4, 3, 2, 1, 0
- B. 5, 4, 2, 1, 0
- C. 5, 3, 1
- D. 5, 2, 0
- E. None of the above

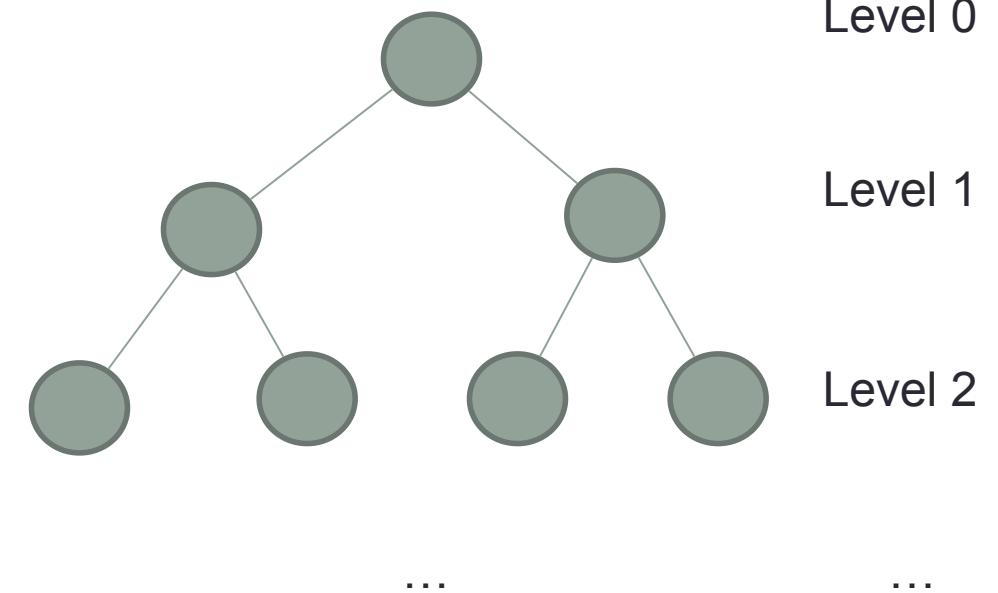

Add a new key with value 4 to the tree represented by this vector

1	2	3	20	5	7	
---	---	---	----	---	---	--

What is the complexity of adding new keys to a complete binary tree?

- A. O(1)
- B. O(log n)
- C. O(n)
- D. None of the above

Show that a complete binary tree is balanced
