Problem: Fibonacci Numbers

Definition:

The Fibonacci numbers are the sequence

1, 1, 2, 3, 5, 8, 13, 21, 34, 55,…

Defined by

$F_0 = F_1 = 1$

$F_n = F_{n-1} + F_{n-2}$ for n ≥ 2

Problem: Given n, compute F_n.

Which implementation is significantly faster ?

A.

B.

```
F(int n){
    if(n <= 1) return 1
    return F(n-1) + F(n-2)
}
```

```
F(int n){
    Initialize A[0 . . . n]
    A[0] = A[1] = 1

    for i = 2 : n
        A[i] = A[i-1] + A[i-2]

    return A[n]
}
```

C. *Both are almost equally fast*

Which implementation is significantly faster ?

A.

B.

```
F(int n){
    if(n <= 1) return 1
    return F(n-1) + F(n-2)
}
```

```
F(int n){
    Initialize A[0 . . . n]
    A[0] = A[1] = 1

    for i = 2 : n
        A[i] = A[i-1] + A[i-2]

    return A[n]
}
```

C. *Both are almost equally fast*

The "right" question is: How does the running time grow?

E.g. How long does it take to compute F(200) recursively?

….let's say on….a supercomputer that can compute 40 trillion operations per sec

How long does it take to compute Fib(200) recursively?

….let's say on…. a supercomputer that runs 40 trillion operations per second

It will take approximately 2^{92} seconds to compute F_{200}.

Time in seconds	Interpretation
2^{10}	17 minutes
2^{20}	12 days
2^{30}	32 years
2^{40}	35000 years (cave paintings)
2^{50}	35 million years ago
2^{70}	Big Bang

What is the main takeaway so far?

How long does it take to compute Fib(200) recursively?

….let's say on…. a supercomputer that runs 40 trillion operations per second

It will take approximately 2^{92} seconds to compute F_{200}.

| Time in seconds	Interpretation
2^{10}	17 minutes
2^{20}	12 days
2^{30}	32 years
2^{40}	35000 years
	(cave paintings)
2^{50}	35 million years ago
2^{70}	Big Bang

Questions of interest:
- Why is Algo A so slow?
- How do we quantify efficiency?
- Is Algo A better than Algo B?
- When will my code finish running?

Why So Slow?

```
F(int n){
    if(n <= 1) return 1
    return F(n−1) + F(n−2)
}
```
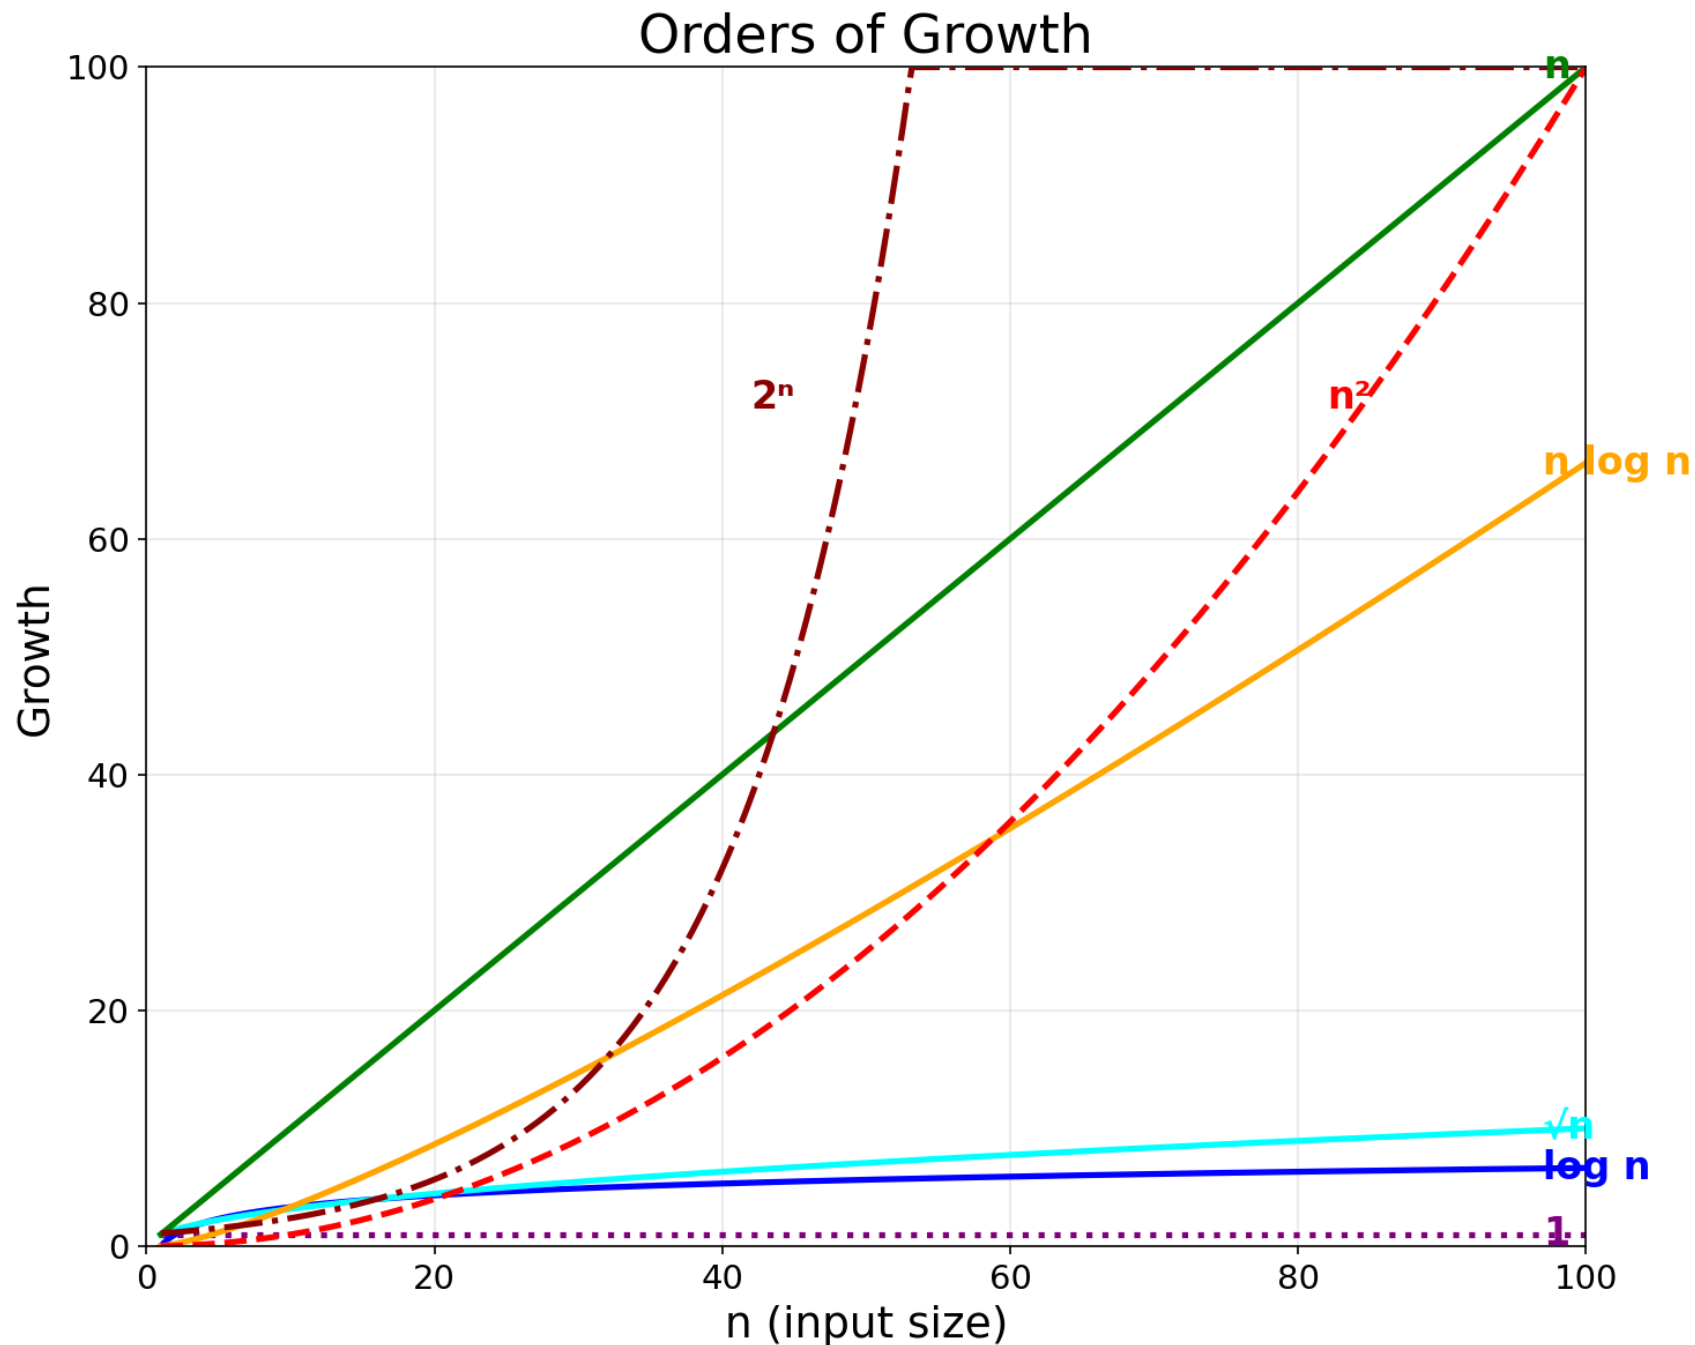

Too many recursive calls.

Which curve represents how the recursive fibonacci function grows?

- An **order of growth** is a set of functions whose growth behavior is considered equivalent.

- Functions that grown similarly belong to the same order of growth

Orders of Growth

ORDERS OF GROWTH ACTIVITY

1. Rank these functions from SLOWEST to FASTEST growth order

   100   n 50n $2n^2$ $n \log n$ 2^n

  ____   ____   ____   ____   ____   ____

2. Which functions belong to the SAME order of growth?

  _____

3. The recursive Fibonacci has ____ order of growth.

4. The iterative Fibonacci has ____ order of growth.

Big-O: Notation to name the order of growth

Order of Growth	Big-O Notation
Constant	
Logarithmic	
Linear	
Linearithmic	
Quadratic	
Exponential	

- 50n and n are both O(n) — same order of growth.
- Big-O captures the growth rate, ignoring constants.

Express in Big-O notation

1. 10000000
2. 3n
3. 6n-2
4. 15n + 44
5. 50nlog(n)
6. n^2
7. n^2-6n+9
8. $3n^2$+4*log(n)+1000
9. 3^n + n^3 +log(3*n)

Common sense rules

1. Multiplicative constants can be omitted: $14n^2$ becomes n^2 .

2. n^a dominates n^b if a > b: for instance, n^2 dominates n.

3. Any exponential dominates any polynomial: 3^n dominates n^5 (it even dominates 2^n).

For polynomials, use only leading term, ignore coefficients: linear, quadratic

Big O running time analysis: clicker

```
/* n is the length of the array*/
int sum(int arr[], int n)
{
    int result = 0;
    for(int i = 0; i < n; i+=2)
        result+=arr[i];
    return result;
}
```

Join iclicker at https://join.iclicker.com/ZHLY

A. $O(n^2)$

B. $O(n)$

C. $O(n/2)$

D. $O(\log n)$

E. None of the above

Iterative Fibonacci Algorithm
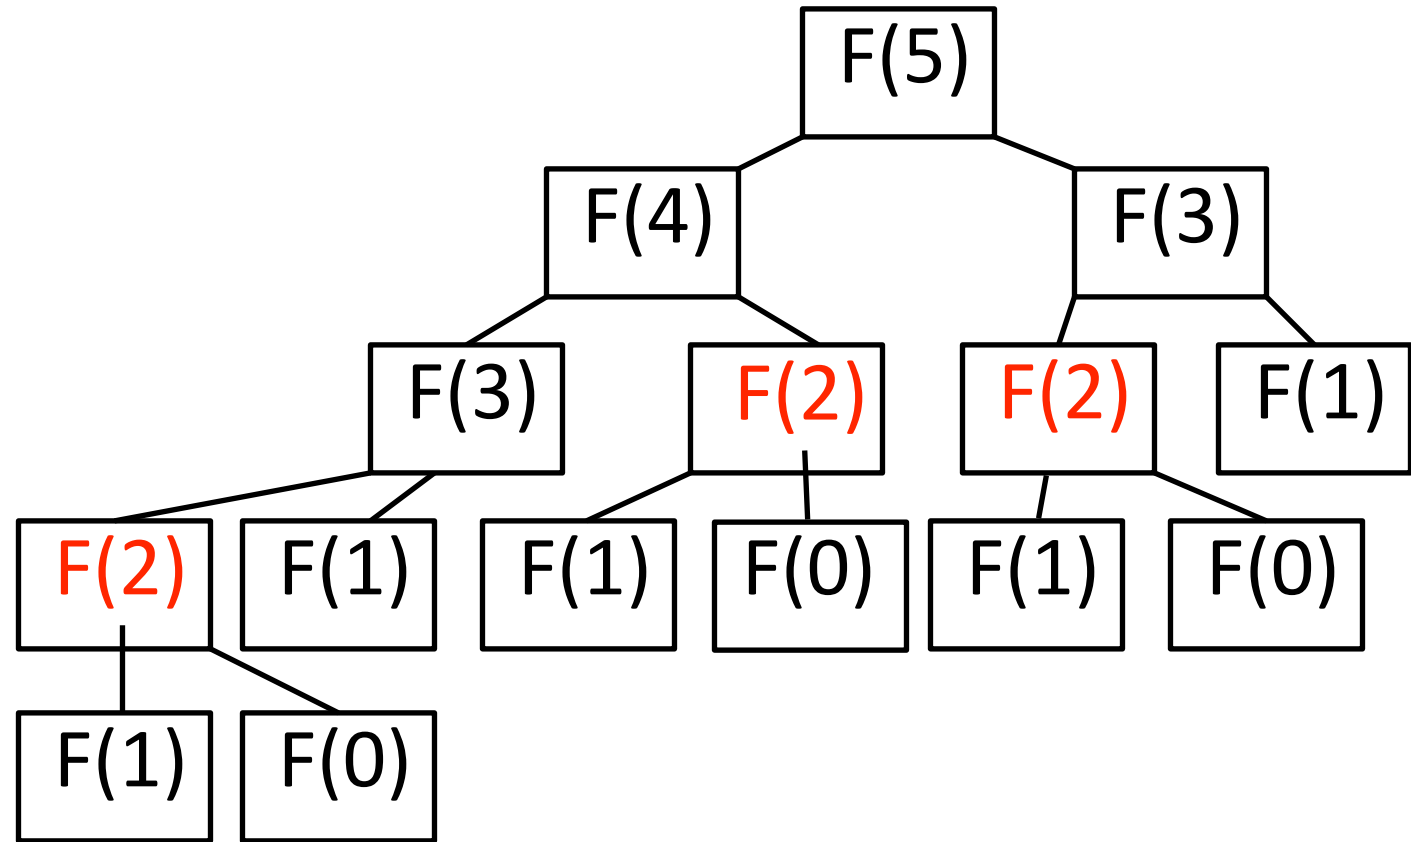

T(n) : running time of F(n)

   : **number of primitive operations to execute F(n)**

```
F(int n){
    Initialize A[0 . . . n]
    A[0] = A[1] = 1

    for i = 2 : n
     A[i] = A[i−1] + A[i−2]

    return A[n]
}
```

Derive $T(n) = O(2^n)$

```
F(int n){
    if(n <= 1) return 1
    return F(n-1) + F(n-2)
}
```

Derive $T(n) = O(2^n)$
